This report has been produced by Premier Analytical Services under a contract placed by the Food Standards Agency (the Agency). The views expressed herein are not necessarily those of the Agency. Premier Analytical Services warrants that all reasonable skill and care has been used in preparing this report. Notwithstanding this warranty, Premier Analytical Services shall not be under any liability for loss of profit, business, revenues or any special indirect or consequential damage of any nature whatsoever or loss of anticipated saving or for any increased costs sustained by the client or his or her servants or agents arising in any way whether directly or indirectly as a result of reliance on this report or of any error or defect in this report.

1. EXECUTIVE SUMMARY

This report refers to work carried out as part of a rolling survey of process contaminants in UK retail foods. The report contains the results for acrylamide and furan levels in food samples purchased between January 2014 and November 2015:

- A total of 526 samples were collected by an independent sampling contractor (Ventress Technical) from a range of retail outlets in seven regions of the UK
- The selection of samples followed a core sampling and analysis plan from a previous acrylamide and furan survey (November 2011- December 2013).
- For the latest survey (2014-2018), all samples were categorised in accordance with the requirements for the submission of data to EFSA^{1,2}.
- Where necessary, foods were cooked or prepared according to the manufacturers' guidelines prior to analysis.
- All analyses were carried out using accredited methods: a total of 518 tests were carried out for acrylamide and 250 for furan.
- For this period, the number of products found to contain acrylamide levels that exceeded European Commission 'Indicative Values' (IV)³ for their food category was 29.

3. INTRODUCTION

Absent in raw food, or the raw materials used to make food, acrylamide and furan are chemical substances produced naturally when some foods are subjected to high temperatures during cooking (including home-cooking) and processing. Regular and prolonged exposure over a lifetime to foods containing high levels of acrylamide and furan has the potential to increase the risk of developing cancer. Experts, including the international Joint Food and Agriculture Organisation and the World Health Organisation Expert Committee on Food Additives (JECFA), have concluded that current global levels of dietary exposure to acrylamide and furan indicate a human health concern⁴. The UK Food Standards Agency (FSA) has concluded that exposure to acrylamide and furan should be as low as reasonably achievable (ALARA). The FSA has produced advice for consumers in relation to acrylamide in food⁵.

3.1 Acrylamide

Acrylamide is a chemical that forms naturally in (mostly) starchy foods during every-day high temperature cooking (as foods lose moisture and temperatures exceed 120°C) such as baking, frying and roasting. It is formed mainly from sugars and the amino acid asparagine, both of which are naturally present in foods. The chemical process that causes this occurs as a minor part of the so called Maillard Reaction; the Maillard Reaction is mainly responsible for the desirable colour and taste of food. Although acrylamide does not occur in foods subjected to lower temperatures and relatively short process times e.g. boiled potatoes, it has been found in a wide range of home-cooked and processed foods, including, bread, coffee, crispbreads, French fries and potato crisps.

There are no statutory maximum acrylamide levels, however the latest European Commission Recommendation⁶ on investigations into the levels of acrylamide in food specifies 'indicative values' (IV) for acrylamide. These IV, which apply to the current 2014-2018 survey period, are not intended as maximum limits but as a trigger to initiate investigations by enforcement authorities into food business operators' understanding of acrylamide and any action they have taken to mitigate its production. Foods that exceed an 'IV' do not trigger enforcement action. Through such investigations it is hoped to gain a better understanding of the practical issues involved. An acrylamide "toolbox" is available to industry to provide guidance on measures to reduce acrylamide levels in various categories of foods. Short extracts of the toolbox have been developed in the form of sector specific brochures and can be found on the Commission website⁷. These brochures are designed to help food business operators to implement those items of the toolbox that are relevant for their sector. The Food

and Drink Federation (FDF) also has recordings of ‘webinars’ (online presentations) on the use of the toolbox that may be of interest to food businesses⁸.

3.2 Furan

Furan is formed from the thermal degradation of sugars, oxidation of polyunsaturated fatty acids or the decomposition of ascorbic acid (vitamin C). It is found in a variety of products, including coffee, prefabricated potato snacks and canned and jarred products which, during processing, have been subjected to a high temperature heat treatment (e.g. roasting, frying, canning etc).

Furan is highly volatile; however once formed as a result of the heat treatment, it cannot evaporate from processed food contained in an airtight sealed pack until the container is opened. Residual furan that may be present in the food after first opening the container may also evaporate over time, although the amount of furan lost will be dependent on the conditions of storage.

Furan has been classified by the IARC as a possible human carcinogen. Evidence indicates that the latter may occur via a genotoxic mechanism. In 2007, the European Commission recommended that member states should carry out monitoring for the presence of furan in heated foods⁹.

3.3 EC Recommendations

This survey was conducted in response to two European Commission Recommendations for pan-European activity on process contaminants: (i) European Commission Recommendation (EU) No. 2010/307 to investigate the levels of acrylamide in food, and in particular to monitor the effectiveness of acrylamide reduction measures as specified in the FoodDrinkEurope toolbox and (ii) European Commission Recommendation (EC) No. 2007/196, to monitor the occurrence levels of furan in foodstuffs.

3.4 European Food Safety Authority

As with previous surveys on acrylamide and furan, all data from this survey will be submitted to the European Food Safety Authority (EFSA). EFSA collates the acrylamide results with those from other Member States and, in the case of furan, these data will be used by EFSA as the basis of developing a risk assessment. EFSA publishes the acrylamide exposure assessments and trend analyses on their website¹⁰.

On 4th June 2015, EFSA published its Scientific Opinion on acrylamide in food¹¹. EFSA agreed with the previous evaluations, that acrylamide in food has the potential to increase the risk of developing cancer. EFSA also considered possible harmful effects of acrylamide on the nervous system and male reproduction, and based

on current levels of dietary exposure, these effects were not considered to be a concern. Further information on acrylamide can be obtained from the EFSA website.

3.5 FSA Surveys

Information and results for all previous surveys can be accessed from the FSA website¹².

The results obtained from this 2014-15 survey form part of a longer term surveillance programme. It is expected that following the current 2014-2018 survey period, further analyses of all data and trends regarding the levels of acrylamide and furan in UK retail foods will be carried out.

4. METHODS

4.1 Sampling

Prior to the commencement of sampling, the FSA agreed a detailed sampling plan with the analytical contractor (Premier Analytical Services) who was responsible for coordinating the purchase and collection of samples (via Ventress Technical) from a wide range of retail outlets including major and smaller supermarkets and independent retailers in the UK.

A total of 526 samples were purchased to cover the 11 Food Categories in line with the requirements of EFSA^{13,14} and the European Commission¹⁵.

Details of the sampling plan are given in Table 4 of the appendices (see section 6).

4.2 SAMPLE PREPARATION AND ANALYSIS

Samples received at the laboratory were prepared and stored according to the Food Standards Agency “Guidelines for undertaking surveys”¹⁶. Potato products from Food Category 3 and Popcorn from Food Category 10 were cooked according to manufacturers’ guidelines prior to the determination of acrylamide; because of the volatile nature of furan, coffee and coffee substitutes were tested for furan before and after preparation for consumption according to manufacturer’s guidelines. Further details of the sample preparation procedures used are given in the appendices (see section 6.2 and Table 5 and Table 6).

Analysis of samples for the 2014-15 survey was carried out using UKAS accredited methods: the measurements of acrylamide and furan were based on the guidelines laid down in Commission Recommendations 2007/331/EC and 2007/196/EC. All test results were obtained from methods that used labelled isotope internal standards for recovery correction. Further details of the methods together with the analytical quality assurance procedures and measurement uncertainty can be found in the appendices (see sections 6.2 and 6.3).

5. RESULTS SUMMARIES

A total of 526 samples were received over the period January 2014 - November 2015 for the analysis of acrylamide and furan in accordance with the test requirements given in Table 1.

Table 1. Summary of samples received (Jan 2014 - Nov 2015) and tests undertaken

Food category / sub category ^a	Description	Number of samples received	Analyses			
			acrylamide		furan	
			As received	As consumed	As received	As consumed

5.1 ACRYLAMIDE

A summary of acrylamide concentrations (mean, range, number of samples and IV) measured in each of the main categories and sub-categories of the 2014-15 survey samples is given in Table 2: 518 tests were carried out for acrylamide and the individual sample results for each category can be found in 6.4 of the Appendices.

Table 2. Summary of acrylamide concentrations in each product category / sub-category

5.2 FURAN

A total of 250 tests for furan were carried out on 210 samples from the 2014-15 survey. A summary of the furan concentrations (mean and range) by product category is shown in Table 3. The individual sample results for each category can be found in 6.4 of the Appendices.

Table 3. Summary of furan concentrations (mean and range) as received / consumed by product category

6.2 SAMPLE PREPARATION DETAILS AND ANALYTICAL METHODS

6.2.1 Sample preparation

All samples were prepared according to the Food Standards Agency “Guidelines for undertaking surveys”²⁴. Where practical, digital images (samples and packaging) were recorded and all packaging retained.

Potato products for home cooking from Category 3 and popcorn (Category 10) were cooked according to the manufacturers’ guidelines using domestic appliances e.g. oven, grill, microwave, deep fat fryer (see Table 5). The grill and oven were preheated for 5-10 minutes and a single layer of the product was applied to a baking tray (placed in middle of oven) or mesh grill pan respectively; samples were typically turned at half of the recommended cooking time. Pure sunflower oil was used for frying.

Coffee and coffee substitute samples were prepared according to the manufacturers guidelines given on the packaging: retail domestic coffee preparation equipment was used as required, e.g. a cafetiere or espresso coffee maker (see Table 6).

6.2.1.1 Homogenisation

Samples requiring furan analysis, e.g. jars and packets were separated and retained for individual processing; coffee and coffee substitutes prepared for consumption were analysed immediately after the preparation cycle. These samples were not subjected to bulk homogenisation as this would have resulted in significant losses of volatile furan.

Where practical, entire samples (approximately 1kg) were homogenised using a food processor:

- Potato products from Categories 1, 3 and 10 and liquorice from category 11 were homogenized with water (1:2 sample/water w/w) using a high speed blender or food processor.
- Canned products were drained & stones removed prior to homogenization.
- A domestic cheese grater was used for the chocolate.
- Bread from Category 4 was air-dried (weight loss recorded) prior to homogenising.
- Category 7 and 9 samples (ground/milled products) were mixed thoroughly prior to analysis
 - A coffee grinder was used for the whole coffee beans.

An aliquot of the homogenised sample was taken for analysis while the remainder was divided into four pots and stored at -18°C.

6.2.1.2 Homogeneity testing

Representative samples from Categories 1-11 were selected at random and the homogeneity determined by replicate (6) sodium analyses. This was based on the assumption that both sodium and the analytes of interest

²⁴ Guidelines for undertaking surveys. Available at:
<https://www.food.gov.uk/sites/default/files/multimedia/pdfs/fsasurveysguidance.pdf> [accessed June 2015]

had an equivalent distribution in these samples. Samples were confirmed as homogeneous by comparing the relative standard deviation (RSD) of the replicate measurements with that obtained from method control samples using a statistical F-test.

Samples (2-3 g) were treated with hot concentrated nitric acid prior to determination by atomic absorption spectroscopy on a PE 2100 (Perkin Elmer, USA) according to the procedure of Gorsuch²⁵. Each batch was analysed with a blank and an in-house reference material.

Table 5. Details of the domestic cooking conditions

6.2.2 Acrylamide analysis by GC/MS/MS

Acrylamide was determined as the brominated derivative, 2-bromopropenamide, according to the method of Hamlet and Sadd²⁶.

Method performance (typical): limits of detection (LOD) and quantification (LOQ) were 0.5 and 3.0 µg/kg respectively; the estimated value for the method uncertainty (single determination) was: ±14% at 49 µg/kg (expanded relative uncertainty with a coverage factor of 2). A summary of the method performance data from this survey can be found in Table 7.

6.2.3 Analysis of furan by GC/MS

Furan was measured in samples using a headspace method adapted from the procedure of Becalski *et al*²⁷. Pre-chilled samples were homogenised at 3°C with deionised water and an aliquot was contained in a headspace vial. Deuterium labelled furan (internal standard) was added and the samples incubated at 35°C prior to sampling the headspace for GC/MS analysis. Because of the volatile nature of furan all samples were analysed in duplicate: either single analyses of duplicate packs or duplicate analyses of single packs (depending upon availability).

Method performance (10g sample, typical): The LOD and LOQ were 1 µg/kg and 2.5 µg/kg respectively (unless indicated otherwise in the results); the estimated uncertainty for a single determination over the concentration range 20-100 µg/kg furan was ±20% (expanded relative uncertainty with a coverage factor of 2). A summary of the method performance data from this survey can be found in Table 7.

6.3 ANALYTICAL QUALITY ASSURANCE

All analyses were performed by trained staff in a UKAS accredited laboratory operating an internal audit and review process. All the test methods were all validated in-house and accredited by UKAS (ISO 17025).

Each batch of samples included a procedural blank and an In-House Reference Material (IHRM) and / or spiked sample. Method performance was monitored by assessing the data from IHRMs and / or spiked reference materials in accordance with the rules governing Shewhart control charts²⁸ (this data is summarised in Table 7). The laboratory also participated in the FAPAS proficiency testing schemes available for acrylamide and furan (see Table 8). In addition, 10% of all samples were subjected to a repeat analysis: acceptance criteria for reporting of all results was for the duplicate measurement to be within ±10% of the first measurement.
